#### Abstract

In JQSRT 305 (2023) 108596 we have recently published the discovery of two energy levels of the Pr atom that exhibit strong J-mixing. Additionally, we present here the manifold of observed hyperfine (hf) structure patterns. Their appearance of these patterns is not solely determined by the J-values of the combining upper levels; the composition of their wave functions also plays a cruical role. In total, we identified 49 transitions involving the Jmixed levels, and laser-spectroscopic investigations were conducted for 46 of them. Notably, 13 upper energy levels are reported for the first time in this study. We hope that this investigation will serve as a catalyst for semiempirical or ab-initio calculations aimed at explaining these observations.

## 1. Introduction

During extended work conducted by the laser spectroscopy group at Graz University of Technology, Institute for Experimental Physics, we made a noteworthy discovery of two energy levels. These levels exhibit a unique behavior, resembling both $J=15 / 2$ and $J=13 / 2$ simultaneously [1]. The historical context of hyperfine (hf) structure investigations on the Praseodymium atom ( $Z=59$; the only stable isotope has mass number 141 and nuclear spin quantum number $I=5 / 2$ ) can be found in the preceding paper [1], and therefore, it will not be reiterated here. The same applies to the experimental particulars. All the spectra presented in this study were acquired by scanning the frequency of narrow-band laser light across a spectral line and observing the resultant laser-induced fluorescence (LIF).
${ }^{141} \operatorname{Pr}$ has a relatively high nuclear magnetic moment and shows a wide hyperfine splitting for many lines, thus in Doppler-limited laser spectroscopy most of the hf components can be resolved and described by the hf structure constants of upper and lower levels. On the other hand, the nuclear electric quadrupole moment of ${ }^{141} \mathrm{Pr}$ is small; thus, only in very rare cases, the electric hyperfine structure constant B leads to noticeable shifts of the hf components. In this paper, with exception of one level, all constants B are treated to be zero.

The energy levels given in [1] are listed in Table 1.
For handling the observed lines and patterns with the classification program "Elements" [2,3] we use 4 auxiliary lower levels, given in

Table 2.
The new J-mixing levels are observed only as lower levels of the investigated transitions. We assume they have a metastable character, thus their population in the used source of free Pr atoms (low-density gas discharge) seems to be high. This would also explain the fact that more than 40 transitions to upper levels could be excited by laser light in the relatively small spectral ranges accessible by our laser systems ( 5583 to $6642 \AA$ and 7092 to $7422 \AA$ ). We presume that lot of other transitions could be observed when enlarging these wavelength ranges.

Since the J-mixing levels behave as having $J=15 / 2$ and $13 / 2$ at the same time, we calculated first transition wavelengths to known upper levels having $J_{\text {up }}=11 / 2$ to $17 / 2$, corresponding to $\Delta J=0, \pm 1$. Setting the laser wavelength to the calculated value, we searched for LIF lines. If we found such signal, we scanned the laser frequency across the line and recorded the hf pattern. But by extending the investigations, we also found transitions to new, not previously known energy levels.

In normal hf patterns, the strongest components are determined by the rule $\Delta \mathrm{F}=\Delta \mathrm{J}$, and only one group of these components is observed. The observed patterns in which the J-mixed levels are involved do not follow this rule, but we can select the auxiliary level(s) needed to describe the observed hf spectra using this rule.

The observed patterns are named following the observation of the main intense groups of hf components. For example, from $J_{u p}=11 / 2$ we observe only transitions to $J_{\text {low }}=13 / 2$, since the rule $\Delta \mathrm{J}= \pm 1,0$ holds, and thus to levels $\{1 \mathrm{~b}\}$ and $\{2 \mathrm{~b}\}$. Such a scheme is subsequently named

[^0]Table 1
Properties of the new J -mixing levels for which J is no good quantum number.

| No. | Energy $\left(\mathrm{cm}^{-1}\right)$ | Parity | J | A <br> (MHz) | F | Group in Figures |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \{1\} | 15,191.990(10) | odd | 15/2+13/2 | 730(2) | 10 to 4 | A |
| \{2\} | 15,191.238(10) | odd | $15 / 2+13 / 2$ | 666(2) | 9 to 4 (no transitions to $\mathrm{F}=10$ observed) | B |

Table 2
Auxiliary levels used in the classification program "Elements". The absolute uncertainty of the level energy is $0.010 \mathrm{~cm}^{-1}$, but the energy differences have a much lower uncertainty of $0.002 \mathrm{~cm}^{-1}$.

| No. | Energy $\left(\mathrm{cm}^{-1}\right)$ | J | A (MHz) |
| :--- | :--- | :--- | :--- |
| $\{1 \mathrm{a}\}$ | $15,192.068$ | $15 / 2$ | $730(2)$ |
| $\{1 \mathrm{~b}\}$ | $15,191.885$ | $13 / 2$ | $730(2)$ |
| $\{2 \mathrm{a}\}$ | $15,191.381$ | $15 / 2$ | $666(2)$ |
| $\{2 \mathrm{~b}\}$ | $15,191.215$ | $13 / 2$ | $666(2)$ |

101. From $\mathrm{J}_{\mathrm{up}}=13 / 2$ we may observe intense groups resembling to transitions to levels $\{1 \mathrm{a}\},\{1 \mathrm{~b}\}$ and $\{2 \mathrm{~b}\}$; we name such scheme 1101 , and so on. For each of the possible transition schemes, we show one hf pattern (in most cases to the upper level which has the lowest A-factor and thus provides the highest hf splitting).

In Table 3 all observed transitions to the new J-mixing levels are listed. The lower levels are introduced according to Table 2. The transitions are sorted by angular momentum $\mathrm{J}_{\text {up }}$ of the combining upper levels, and within each $J_{u p}$-group by increasing energy of the upper levels. In column 1 the transitions are numbered, and in column 2 the observed scheme (e.g. 1010, see text before) is given. Columns 3-5 contain information about the upper level (J, energy, hf-constant A), and columns $8-10$ contain the same information about the lower level. In column 6 the wavelength of the observed line is given, with two digits after the decimal point, if it is the reading value of our lambdameter (accuracy and resolution $0.01 \AA$ ). If three digits after the decimal point are given, the line is visible in the available FT spectrum [4]. Column 7 contains information on the line intensity. If only "nl" is given, it is a new spectral line not reported earlier in the literature, but not appearing in the FT spectrum. If " nl " is followed by a number, the line is visible in the FT spectrum with this signal-to noise ratio (SNR). If only a number is given (e.g. SNR $=40$ for transition no. 48), the line was reported already by A. Ginibre [5], but not classified by her.

All A-values given in column 5 for the upper levels were determined within this work under assumption that the lower levels have values $A_{\text {low }}=730$ and $A_{\text {low }}=666 \mathrm{MHz}$, respectively. Due to the large number of hf components of the observed patterns, the uncertainty is sometimes lower than reported earlier. In column 11 a reference for the hf constant A of the upper level is given. If the A-value in the cited paper is different from the value given in column 5 , the literature value is also given. In most cases the values agree within the given uncertainties. This is not the case for level $31,642.945 \mathrm{~cm}^{-1}$ (line no.9), for which we claim to have now a better value. For level $32,512.894 \mathrm{~cm}^{-1}$ the uncertainty could be lowered from 15 to 3 MHz .

Some of the upper levels are found during the present investigation. In these cases, the remark "new upper level" is given in column 11. All lines belonging to the new levels can be found in Appendix A. For the new level at $32,420.552 \mathrm{~cm}^{-1}$ it was necessary to introduce a relatively large value of the hf constant $\mathrm{B}(-215 \mathrm{MHz})$ in order to explain all observed hf patterns.

Lines no.1, 24, 25, and 44 are observed as fluorescence lines when transitions in which the upper levels are involved, were excited by laser light. These lines are outside the wavelength ranges of our dye lasers, and thus their hf patterns could not be recorded. For these transitions, only one lower level from Table 2 is selected. The transition wavelength is calculated for no. 24 and no. 44 from the level energies, since the monochromator used for detection of the fluorescence line has a
resolution of only $\pm 2 \AA$ and these two lines are not visible in the FT spectrum.

## 2. Description of the observed patterns

Typical observed hf patterns - all of them show perturbed intensity ratios of the hf components - are presented in Figs. 1-7. In all figures, the experimentally observed patterns are shown in black (traces a). All observed patterns can be well fitted using the levels from Table 3, when allowing arbitrary intensities for the components (traces $b$ in the figures, shown in red). The position and relative intensity of the hf components are shown as bars below trace a. Trace c shows the residual, multiplied by the given factor at the right side of trace $c$. No larger systematic deviations between experimental and fitted curves were observed. This tells us that the perturbation between the two J-mixed levels influences only the intensities, but not the positions of their hf sublevels.

Simulated patterns, which have theoretical intensity ratios of the hf components, are shown in the figures (trace d) in black if $\mathrm{J}_{\text {low }}=13 / 2$ and in blue if $\mathrm{J}_{\text {low }}=15 / 2$. Below the patterns, their center of gravity (cg) is marked by a vertical line.

In the transition schemes shown in the figures, the transitions are drawn in blue for $\Delta J=J_{\text {low }}-J_{\text {up }}=-1$, in black for $\Delta J=0$, and in red for $\Delta J=+1$. If in the experimental trace the weakest components are not observed, the transitions are omitted.

We divide each experimental pattern into group A (transitions to level $\{1\}$ ) and group B (transitions to level $\{2\}$ ). As discussed in ref. [1], we have not observed overlapping hf patterns between the transition to the auxiliary level pairs $\{1 \mathrm{a}\},\{1 \mathrm{~b}\}$ and $\{2 \mathrm{a}\},\{2 \mathrm{~b}\}$. Such overlap would appear for A-values of the upper levels smaller than 300 MHz (the lowest A-value of the upper levels involved here is 395 MHz ). Thus, in all drawings shown, the transitions to pair $\{1 \mathrm{a}\},\{1 \mathrm{~b}\}$ (part A of the figures) are well separated from transitions to $\{2 a\},\{2 b\}$ (part B of the figures).

Additional information in the figures is the excitation wavelength in $\AA$ (integer values) and the A-value of the combining upper level in MHz (left side of trace d). The line numbers corresponding to Table 3 are also given.

### 2.1. Upper level having $J_{u p}=11 / 2$, transition scheme 0101, Fig. 1

From the transition rule for J it follows that the lower level behaves like having $J_{\text {low }}=13 / 2$, and only the auxiliary levels $\{1 \mathrm{~b}\}$ and $\{2 \mathrm{~b}\}$ are necessary for the description. However, the intensity distributions are quite different compared to regular hf patterns. Since the highest F-value of the upper level is $F_{u p}=8$ and the transition rule $\Delta F= \pm 1,0$ holds, no transitions to $\mathrm{F}_{\text {low }}=10$ are observed.

Group A: The transition to level $\{1 \mathrm{~b}\}(A=730 \mathrm{MHz}$, left part in Fig. 1) should have its highest component for transition $F_{u p}-F_{\text {low }}=8-9$ (Fig. 1, trace d), and with decreasing F-values of this sequence falling intensities. But in the experiment (trace a) we observe increasing intensity, reaching the maximal value for transition 4-5. Transition 3-4 then has a little bit lower intensity.

Group B: The calculated hf pattern for transitions to level \{2b\} looks similar to $\{1 \mathrm{~b}\}$, but the spacing of the components is little bit smaller due to the smaller lower A-value ( 666 MHz ) of level $\{2 \mathrm{~b}\}$. But for this group the experimental trace has its highest component for the transition $F_{u p}-F_{\text {low }}=8-9$ as it should be, but the intensities decrease much faster compared to trace d .

Table 3
Observed transitions to the J-mixed levels. The uncertainty of the level energies in col. 4 is $0.010 \mathrm{~cm}^{-1}$, if not otherwise given. E ... energy, wl ... wavelength, SNR ... signal-to-noise-ratio in the FT spectrum, tw ... this work. For the level at $32,420.552 \mathrm{~cm}^{-1}$ below the value A, the value of hf constant B is given.

Fig. 1. Transition from an upper level having $J_{u p}=11 / 2$ (line no. 4 in Table 3), transition scheme 0101. (a) experimental record. (b) Fitted curve. (c) Residual between experimental and fitted curve, multiplied with the factor given on the right side. Below trace (a), the hf components are shown as determined in the fit procedure. (d) Simulation of the pattern with theoretical intensity ratios of the hf components. Since the lower level has $\mathrm{J}_{\mathrm{low}}=13 / 2$, the simulation is shown in black. Left of trace (d) the wavelength (in $\AA$ A as integer value) and the value of the hf constant A of the upper level (in MHz) are given. In the upper part of the figure, the hf level scheme is shown. Since here the highest $F$-value of the upper level is $F_{u p}=8$ and the transition rule $\Delta F= \pm 1,0$ holds, no transitions to $F_{\text {low }}=10$ are observed.

### 2.2. Upper levels having $J_{u p}=13 / 2$ and $15 / 2$

For $J_{u p}=13 / 2$ and $J_{u p}=15 / 2$ all possible transition schemes to the four auxiliary levels are observed. For each scheme, the observed patterns show some similarities, independent of the J-value of the upper level.

### 2.2.1. Transition scheme 0101, Fig. 2

Let us first discuss the case of $\mathrm{J}_{\text {up }}=13 / 2$ and group A. We need only level $\{1 b\}$, having $J_{\text {low }}=13 / 2$, for the description of the pattern. The main components are given by $\Delta \mathrm{F}=\Delta \mathrm{J}=0$. We observe in principle the same behavior as for the low frequency component group in Fig. 1: In contrary to the theoretical pattern (trace d) the intensity of the

Fig. 2. Transition from upper levels having $J_{u p}=13 / 2$ (line no. 5 in Table 3) and $15 / 2$ (line no.39), respectively, transition scheme 0101 . (a) - (d) see Fig. 1. Both lower levels show a behavior like having $\mathrm{J}_{\mathrm{low}}=13 / 2$, but the intensity ratios of the hf components are clearly different from the theoretical ratios. As mentioned in the description of Fig. 1, here the simulated trace is shown in black, since both lower levels have main character $\mathrm{J}_{\text {low }}=13 / 2$.

Fig. 3. Transition from upper levels having $\mathrm{J}_{\mathrm{up}}=13 / 2$ (line no.10) and $15 / 2$ (line no.43), respectively, transition scheme 1010. (a) - (d) see Fig. 1. Both lower levels show a behavior like having $\mathrm{J}_{\text {low }}=15 / 2$. Again, the intensity ratios of the hf components are clearly different from the theoretical ratios. Here the simulated trace is shown in blue, since both lower levels have main character $15 / 2$. The transitions to lower level $\{2 \mathrm{a}\}$ (group B) are observed without the largest theoretical component (to $\mathrm{F}_{\text {low }}=10$ ). At the transition from $\mathrm{J}_{\mathrm{up}}=13 / 2$, the small peaks at the highest offset frequency are at the position of transitions having $\Delta \mathrm{F}=+1$ (theoretical intensities smaller than $0.01 \%$ ).

Fig. 4. Transition from upper levels having $J_{u p}=13 / 2$ (line no.12) and $15 / 2$ (line no.28), respectively, transition scheme 1101. (a) - (d) see Fig. 1. For the description of the low-frequency component group A we need the assumption that transitions to $\mathrm{J}_{\text {low }}=15 / 2$ and $13 / 2$ appear simultaneously (lower levels $\{1 \mathrm{a}\}$, $\{1 \mathrm{~b}\}$ ) with approximately the same intensity. The high-frequency groups B are best approximated as transition to $J_{\text {low }}=13 / 2$ (level $\{2 \mathrm{~b}\}$ ).

Fig. 5. Transition from upper levels having $J_{u p}=13 / 2$ (line no.21) and $15 / 2$ (line no.37), respectively, transition scheme 1110. (a) - (d) see Fig. 1. For the description of the low-frequency component group, we need the assumption that transitions to $J_{\text {low }}=15 / 2$ and $13 / 2$ appear simultaneously (lower levels $\{1$ a\} and $\{1 \mathrm{~b}\}$ ), but with a different intensity behavior compared to the scheme 1101 (Fig. 4). The high-frequency groups are best approximated as transition to $\mathrm{J}_{\mathrm{low}}=15 / 2$ (level \{2a\}, without transitions to $\mathrm{F}_{\text {low }}=10$ ).

Fig. 6. Transition from upper levels having $J_{u p}=13 / 2$ (line no.19) and $15 / 2$ (line no. 34), respectively, transition scheme 1111. (a) - (d) see Fig. 1. Here we need all four auxiliary levels to explain the appearance of hf components with high intensities.

Fig. 7. Transition from an upper level having $J_{u p}=17 / 2$, transition scheme 1010 (line no.47). (a) - (d) see Fig. 1. Both lower levels show a behavior like having $J_{\text {low }}=15 / 2$, but the intensity ratios of the hf components are again clearly different from the theoretical ratios. Components with $\Delta \mathrm{F}=-1$ have theoretical intensity ratios $<1 \%$ and are not shown, since no corresponding experimental transitions were found.
components is growing instead of decreasing. As usual for transitions having $\Delta \mathrm{J}=0$, components with $\Delta \mathrm{F}=+1$ and $\Delta \mathrm{F}=-1$ are visible on both sides of the main component group. Due to the relatively large Avalue of the upper level ( $A_{u p}=609 \mathrm{MHz}$ ), the $\Delta \mathrm{F}=-1$ components overlap and form an intense peak. $\mathrm{J}_{\mathrm{up}}=13 / 2$, group $B$ : The transitions to level $\{2 \mathrm{~b}\}$ show more or less regular intensity distribution, but with a much faster intensity decrease within the $\Delta \mathrm{F}=0$ group.

With the upper level having $J_{u p}=15 / 2$, the patterns look quite similar, but the role of the $\Delta F=0$ group in the case of $J_{u p}=13 / 2$ is now played by the groups $\Delta \mathrm{F}=-1$, and the component group $\Delta \mathrm{F}=+1$ is not noticeable in the experimental trace.

### 2.2.2. Transition scheme 1010 , Fig. 3

In contrary to the pattern discussed in paragraph 2.2 .1 , here the transitions to $\mathrm{J}_{\text {low }}=15 / 2$ dominate. $\mathrm{J}_{\mathrm{up}}=13 / 2$, group A: The observed experimental pattern (trace a) is close to the theoretical one (trace d), but with decreasing F -values the intensity decrease is much faster. For group $B$ the intensities of the components are increasing instead of decreasing, and the transition to $\mathrm{F}_{\text {low }}=10$ is missing.
$J_{\text {up }}=15 / 2$ : In group A now on both sides of the group of strong components weaker components with $\Delta \mathrm{F}= \pm 1$ are visible. Group B behaves similar as for $J_{u p}=13 / 2$. Again no transition to $F_{\text {low }}=10$ could be found.

### 2.2.3. Transition scheme 1101, Fig. 4

Here for the description of group A we need both lower levels, $\{1 \mathrm{a}\}$ and $\{1 \mathrm{~b}\}$, while for group $B$ only lower level $\{2 \mathrm{~b}\}$ is required. All components of group A have approximately the same intensity.
2.2.4. Transition scheme 1110, Fig. 5

As discussed in Section 2.2.3, we need both lower levels, $\{1 \mathrm{a}\}$ and $\{1 \mathrm{~b}\}$, for the description of group A, while in group B only lower level

Fig. 8. Main types of observed most intense hf component groups. Explanation see text. Red: simulation of the experimentally observed patterns. For comparison patterns with theoretical intensity rations are show. For the types a-c $J_{\text {low }}=15 / 2$ (blue) was assumed; for type d we need both, $J_{\text {low }}=15 / 2$ and $13 / 2$ (black).

| 6 | 1111 | 15/2, В | 15/2 | \{2a\} | 0 | 0 |
| 7 | 1010 | 17/2, B | 15/2 | \{2a\} | -1 | -1 |
| Type d: Nearly uniform component intensity |  |  |  |  |  |  |
| 4 | 1101 | 13/2, A | 15/2, 13/2 | \{1a\}, \{1b \} | +1, 0 | +1, 0 |
| 4 | 1101 | 15/2, A | 15/2, 13/2 | \{1a\}, \{1b \} | $0,-1$ | 0, -1 |

$\{2 a\}$ is present. In contrary to scheme 1101, the transitions to $\{1 a\}$ show a fast decrease of the intensities, and to \{1b\} nearly same but smaller intensities. The intensities of the components in group B show an increase in intensities, in contrary to the theoretical pattern.

### 2.2.5. Transition scheme 1111, Fig. 6

Here we need all four auxiliary levels for the best description of the observed patterns. In group A transitions to auxiliary level \{1a\} shows fast decreasing intensities, to level $\{1 \mathrm{~b}\}$ increasing intensities. In group B both transitions to $\{2 \mathrm{a}\}$ and $\{2 \mathrm{~b}\}$ are present with high intensities. Components to $\{2 \mathrm{a}\}$ show increasing intensities compared to the theoretical pattern, and transitions to $\{2 \mathrm{~b}\}$ a much faster decrease.

### 2.3. Upper level having $J_{u p}=17 / 2$, transition scheme 1010, Fig. 7

In this case, only transitions to lower levels having $J_{\text {low }}=15 / 2$ are observed ( $\{1 \mathrm{a}\},\{2 \mathrm{a}\}$ ). Compared to transitions from $\mathrm{J}_{\text {up }}=11 / 2$ (Fig. 1), the observed patterns of groups A and B are now exchanged.

## 3. Types of most intense patterns

In Figs. 1-7 we observe some generalized types of most intense hf patterns. These types are depicted in Fig. 8.

### 3.1. Type a

Strong decrease of the intensities of the main component group. Here the hf components show more or less usual behavior, but, compared to theoretical intensity ratios, the intensities of the components are
decreasing much faster with decreasing quantum numbers F

### 3.2. Type $b$

Increase and decrease of the intensities in the main component group. In contrary to the theoretical pattern, the highest component is not observed at the place where the theoretical pattern has its highest component (highest F-values). Instead, the intensities are first increasing and reach most intensity at the last minus one component. The last component then has little lower intensity. This type is observed at transitions within group A (to levels $\{1 \mathrm{a}\},\{1 \mathrm{~b}\}$ ).

### 3.3. Type $c$

For transitions to level \{2a\}) within group B we never have observed transitions to $F_{\text {low }}=10$. The intensities grow like for type $b$, but here, the last component is the most intense one.

### 3.4. Type $d$

For the transition scheme 1101, a nearly uniform intensity of the hf components within group A (transitions to levels \{1a\} and \{1b\}) is observed.

The types and their appearance in the figures, together with values $\Delta \mathrm{J}$ and $\Delta \mathrm{F}$, are listed in Table 4.

## 4. Comments on the interpretation of the spectra

In ref. [1] we have discussed also other possibilities of interpretation

Table 5
Observed transitions in which the newly found energy levels are involved (transitions to the J-mixed levels: see Table 3). E ... energy, wl ... wavelength, C ... comment: $\mathrm{nl} .$. new line, cl ... known line which could be classified, f ... line observed as fluorescence line after laser excitation, e ... laser excited transition, SNR ... signal-to-noise-ratio in the FT spectrum. "-" in col. 6 means that the line is not visible in the FT spectrum or hidden in a complicated blend situation. For the level at $32,420.552$ $\mathrm{cm}^{-1}$, below the A-value the value of hf constant B is given.

Fig. 9. Transitions from upper levels having $J=11 / 2$, transition scheme 0101. For the meaning of the traces see Fig. 1. Additionally, the line numbers from Table 3 are given. Inserted are wavelength (in $\AA$, only integer values) and A-factor of the upper level (in MHz).

Fig. 10. Transitions from upper levels having $J=13 / 2$, transition scheme 0101.

Fig. 11. Transitions from upper levels having $J=13 / 2$, transition scheme 1010.

Fig. 12. Transitions from upper levels having $J=13 / 2$, transition scheme 1101. In line no. 13 between the two transitions discussed here, a blend line is recorded (transition $31,801.951 \mathrm{~cm}^{-1}, \mathrm{~J}_{\text {up }}=17 / 2$, even parity, $\mathrm{A}_{\text {up }}=503(1) \mathrm{MHz}-15,194.595 \mathrm{~cm}^{-1}, \mathrm{~J}_{\text {low }}=15 / 2$, odd parity, $\mathrm{A}_{\text {low }}=343$ (2) MHz). Both upper and lower level of the blend line differ in energy by less than $4 \mathrm{~cm}^{-1}$ from the levels leading to the structures of line no.13. Thus - due to the limited resolution of the monochromator used in the experiment, an excitation- and a LIF-blend appears.

Fig. 13. Transition from an upper level having $J=13 / 2$, transition scheme 1110.
of the observed hf spectra. We have excluded that saturation effects are responsible for the observed unusual intensity behavior of the hf components and the possibility, that radationless transitions are responsible for the observations.

In all spectra shown in this study, the frequency position of the observed hf components can be explained with help of the four auxiliary levels. The curves fitting the experimental structures are gained without any conditions for the component intensities, these were free parameters in the fit. Facts that we can state are:
(i) For the description of group A we need F-values of the new level $\{1\}$ from $\mathrm{F}_{\text {low }}=10$ to $\mathrm{F}_{\text {low }}=4$, in contradiction to regular levels, while for group $B$ a new level $\{2\}$ having $\mathrm{F}_{\text {low }}$-values between 9 and 4 is necessary. Nevertheless, some patterns of group B are similar to transitions to $\mathrm{J}_{\text {low }}=15 / 2$ (auxiliary level \{2a\}), but without observation of transitions to $\mathrm{F}_{\text {low }}=10$.
(ii) The simulations shown in the figures as traces d correspond to regular hf dipole-transitions. These simulations are shown for comparison only, and we named the spectra (e.g. 1110) after the similarity of the observed to the simulated patterns.
(iii) We cannot exclude that some of the patterns may be better described assuming multipole transitions. A clarification of this point would need extended theoretical investigations which are not available presently.

## 5. Conclusion

The hf patterns of transitions from upper even-parity energy levels to the J-mixed odd-parity energy levels at $15,191.990$ (10) and $15,191.238$ (10) $\mathrm{cm}^{-1}$ (having simultaneously $J=15 / 2$ and $13 / 2$ ) were investigated. Surprisingly, the hf patterns do depend not only on the J-value of the upper levels. It appears that their wave function composition also plays an important role. For $J_{u p}=11 / 2$ and $J_{u p}=17 / 2$ the selection of the auxiliary levels, introduced for use of our classification program, follows strictly $\Delta J= \pm 1$. For $J_{u p}=13 / 2$ and $15 / 2$, several structures, in which two, three or even four of the auxiliary levels are best describing the most intense component groups, were observed. Unfortunately, no recent parametric fit of the wavefunction of Pr levels is available; the only published paper is from the year 2003 [14] and contains calculated hf constants, but not the wavefunction composition of the treated levels. Thus we see an urgent need for new semi-empirical parametric studies of the Pr atom, including all energy levels discovered in the last two decades.

Imran Siddiqui is thankful to the University of Karachi and to Graz University of Technology for providing fundings during his PhD- and

PostDoc-periods in Graz. Shamim Khan and Syed Tanweer Iqbal are thankful to the Higher Education Commission (HEC) Pakistan and to Sindh Literacy Department, Government of Sindh, Pakistan.

## Appendix A

In Table 5 all observed transitions, in which the newly found energy levels are involved, are listed (with exception of the lines given already in Table 3). The levels are arranged due to their angular momentum $J_{u p}$, and within each group by increasing energy. The uncertainty of the energies is $0.010 \mathrm{~cm}^{-1}$. The wavelength values in col. 4 are calculated from the level energies or come from the reading of our lambdameter (accuracy $\pm 0.01 \AA$ ), if two digits after the decimal point are given. For lines which wavelength could be determined from the FT spectrum, three or four digits after the decimal point are given.

## Appendix B

In the appendix the hf patterns of all transitions, for which laser excitation was successful, are shown (Figs. 9 to 21). If for one type (e.g. 0101) several lines are observed, they are sorted by increasing A-factor of the upper level. The splitting of two hf components having the same value $\Delta \mathrm{F}$ decreases with increasing value of $\mathrm{A}_{\text {up }}$, if $\mathrm{A}_{\text {low }}$ is the same. If the value of $A_{\text {up }}$ is close to $A_{\text {low }}$, some components are overlapping. A level
scheme is given only for the line with the smallest value of $\mathrm{A}_{\text {up }}$ (largest splitting of the hf components).
